Abstract: Nozzle reaction and hose tension are analyzed using conservation of fluid momentum and assuming steady, inviscid flow and a flexible hose in frictionless contact with the ground. An expression that is independent of the bend angle is derived for the hose tension. If this tension is exceeded owing to anchor forces, the hose becomes straight. The nozzle reaction is found to equal the jet momentum flow rate, and it does not change when an elbow connects the hose to the nozzle. A forward force must be exerted by a firefighter or another anchor that matches the forward force that the jet would exert on a perpendicular wall. Three reaction expressions are derived, allowing it to be determined in terms of hose diameter, jet diameter, flow rate, and static pressure upstream of the nozzle. The nozzle reaction predictions used by the fire service are 56 – 90% of those obtained here for typical firefighting hand lines.

Keywords: *fluid mechanics; hose tension; hydraulics; kickback; spray*

Introduction

Nozzle reaction (or kickback) is the force exerted on a firefighter or other anchor by a stationary spraying nozzle supplied by a flexible hose. The reaction direction is opposite that of the jet. Nozzle reaction can limit water delivery rate and increase firefighter air consumption rate, fatigue, and injuries [1-4]. Between 2007 and 2011 in the United States, an annual average of 13,795 firefighting injuries resulted from handling of charged hose lines, of which 3,565 were associated with overexertion [5]. Nozzle reactions have caused fatalities of pressure washer operators [6].

Hose tension is the longitudinal force supported by the walls of a flexible hose. The design and selection of hoses depends on reasonable estimates of hose tension.

Although many publications have analyzed firefighting nozzle reactions, none has considered the steady case of an anchored nozzle with an arbitrary hose bend angle, and none has addressed hose tension. The objective of this manuscript is to provide these analyses.

The fluid mechanics of nozzle reaction has attracted notable researchers including Mach, Prandtl, and Feynman [7-9]. Fay [10] and Lautrup [11] showed that the reaction for a nozzle attached to a flexible hose via a 90° elbow equals the jet momentum flow rate, a finding that also is obtained when the solution of Prandtl [8] is applied to a 90° bend.

Nozzle reaction expressions are provided by the NFPA handbook and elsewhere [1-4,12,13] and are widely used by the fire service. Unfortunately, no derivation or identification of the assumptions exists and recent publications have questioned these expressions [14,15]. This uncertainty may be increasing the reactions firefighters encounter and impeding the development of low-reaction nozzles [16].

A common problem considered in fluid mechanics textbooks is that of the tension between a spraying nozzle and a fixed metal pipe [17-19]. Several textbooks [10,11,14,20,21] claim that the same solution applies when the pipe is replaced with a flexible hose. However, this problem has no steady solution because an unrestrained nozzle will flail around unsteadily. A firefighter or another anchor must push forward on the nozzle to prevent flailing.

Past work has noted that no general and correct solution for firefighting nozzle reaction exists [15,22]. For example, Albertson et al. [23] neglected the contribution of fluid momentum to hose tension and nozzle reaction, which is not valid for typical firefighting. Nazarenko [14] considered a case where an external force is applied to the hose far from the nozzle, but this has no steady solution and is different from firefighter practice. Recent work [14,15] questioned the direction of nozzle reactions when a hose is held perfectly straight, but this is impossible in practice.

The following analysis was undertaken to address the absence of a general solution for firefighter nozzle reaction. Simplifying assumptions (including steady inviscid flow, no gravity, and a flexible hose in frictionless contact with the ground) are made such that this analysis can proceed using elementary fluid mechanics. The resulting expressions are compared with the predictions in use by the fire service and with the limited available measurements.

Hose Tension

Hose tension is a parameter of interest to hose designers and users. It must be solved for before performing a control-volume analysis of firefighter nozzle reaction. To the authors' knowledge, no published solution exists for hose tension.

An analysis of tension in a bent hose is developed here assuming that the flow is (1) steady, (2) inviscid, and (3) incompressible laminar plug flow, with (4) no external longitudinal forces, such as gravity. Furthermore, the hose has (5) a constant inside diameter, is (6) flexible for bending but does not stretch in the circumferential or longitudinal directions, and is (7) in frictionless contact with the ground.

For these assumptions, conservation of linear fluid momentum [17-21] can be expressed as

$$\sum_{cs} \vec{F}_{cv} = \int_{cs} \vec{v} \rho \vec{v} \cdot \hat{n} dA, \quad (1)$$

where A is the area, cs is the control surface, \vec{F}_{cv} are all the external forces acting on the control volume, \hat{n} is the unit normal vector pointing outward, \vec{v} is the velocity, and ρ is the fluid density.

Consider a segment of a bent hose with fluid flowing from stations 1 to 2. The bend angle, θ , can be any non-zero angle. The control volume, which includes the hose and its contents, is acted upon by four external forces. These are the inlet and outlet hose tensions, \vec{T}_1 and \vec{T}_2 , and the pressure forces, $-p A_1 \hat{n}_1$ and $-p A_1 \hat{n}_2$, where A_1 is the cross-sectional area of the hose interior and p is the gage static pressure. For this control volume, Eq. (1) yields

$$\vec{T}_1 + \vec{T}_2 - p A_1 (\hat{n}_1 + \hat{n}_2) = \rho A_1 (\vec{v}_1 \vec{v}_1 \cdot \hat{n}_1 + \vec{v}_2 \vec{v}_2 \cdot \hat{n}_2). \quad (2)$$

Separating Eq. (2) into its x and y components yields

$$-T_1 + T_2 \cos \theta + p A_1 (1 - \cos \theta) = \rho A_1 v^2 (\cos \theta - 1), \text{ and} \quad (3)$$

$$(T_2 - p A_1 - \rho A_1 v^2) \sin \theta = 0, \quad (4)$$

where T_1 and T_2 are the magnitudes of their associated vectors and v is the scalar velocity. The $\sin \theta$ term in Eq. (4) cancels for any nonzero θ . There is no unique solution when $\theta = 0$, i.e., when the hose is perfectly straight. For any non-zero θ , combining Eqs. (3) and (4) yields $T_1 = T_2$, defined here as the scalar hose tension T , and

$$T = p A_1 + \rho Q^2 / A_1, \quad (5)$$

where Q is the volumetric flow rate.

According to Eq. (5), the bent hose tension is independent of the bend angle for any non-zero bend angle. In practice the hose tension cannot be reduced by holding the end of the hose perfectly straight [14,15] because even an infinitesimal bend would yield the tension of Eq. (5). Hose tension is not higher for a 180° bend than for a 90° bend, as claimed by [15]. Although a bent hose tension lower than that of Eq. (5) is impossible, a higher hose tension will result if external forces pull the hose taught and straight.

In practice a streamwise pressure drop will cause a decreasing T with distance. For a bent hose, the balance between p and T is such that the combined walls and contents are neither in tension nor compression.

Nozzle Reaction

Having solved for the hose tension, a control-volume analysis of the nozzle reaction is now possible. Assumptions (1) – (7) are again invoked such that the hose tension is given by Eq. (5). Additionally, it is assumed that (8) the jet consists of plug flow near the discharge, and (9) the contraction coefficient [18] is unity.

Two configurations are considered. The standard configuration involves a nozzle connected directly to a flexible hose. The other configuration includes an elbow with a bend angle, θ , between the nozzle and the hose. This configuration is of interest because some manufacturers sell elbow-nozzle combinations [24,25] and because a 90° bend, as considered by several researchers [10,11,26], can facilitate nozzle reaction experiments.

For either control volume, Eq. (1) yields:

$$-(p_1 - p_2) A_1 \hat{n}_1 + \vec{T} + \vec{F} = \rho A_1 \vec{v}_1 \vec{v}_1 \cdot \hat{n}_1 + \rho A_2 \vec{v}_2 \vec{v}_2 \cdot \hat{n}_2, \quad (6)$$

where \vec{F} is the anchor force vector, which is equal and opposite to the nozzle reaction, \vec{R} .

Combining Eqs. (5) and (6) shows that, for both configuration, the direction of \vec{R} is opposite to the direction of the jet. In other words, a firefighter or other anchor must push on the nozzle in the direction of the jet and \vec{R} has no component perpendicular to the jet. For both configurations the magnitude of the nozzle reaction is

$$R = \rho Q^2 / A_2. \quad (7)$$

According to Eq. (7), the reaction for a nozzle supplied by a bent hose is the jet momentum flow rate. Others obtained the same result for hoses [10,11] and metal pipes [26], but only considered bends of 90°. Equation (7) also appears in a nozzle catalog [25], but without attribution or explanation. No past study has derived Eq. (7) for an arbitrary bend angle or showed that \vec{R} has no component perpendicular to the jet.

A simple scenario yields an independent derivation of Eq. (7). Consider a pumper truck, a hose, and a spraying nozzle held by a firefighter. The hose is flexible, bent, and in frictionless contact with the ground such that it is anchored horizontally only at the pumper and at the firefighter's hands. The water jet impinges on a perpendicular vertical wall. External horizontal forces can act in three locations: where the pumper contacts the ground, at the firefighter's hands, and where the jet strikes the wall. In steady state, the sum of these forces is zero. Because the pumper's orientation cannot transmit down the hose, there can be no horizontal force where the pumper contacts the ground. The two other external forces must be equal and opposite. In other words, the firefighter's hands exert the forward force of Eq. (7) on the nozzle because the wall exerts a backward force of this magnitude on the jet.

Some manufacturers [24,25] suggest adding an elbow between the hose and the nozzle to reduce the nozzle reaction. Equation (7) shows this has no effect on the magnitude or direction of the reaction. In practice an elbow may allow friction between a stiff hose and the ground to support part of the nozzle reaction, but such effects are beyond the present scope.

The expression of Eq. (7) can be plotted for representative conditions, where the curves correspond to different jet diameters, d_2 , defined according to

$$A_2 = \pi d_2^2 / 4. \quad (8)$$

Vertical lines can be shown that correspond to NFPA requirements for the initial attack line and the backup line, 400 and 750 lpm, respectively [27]. A horizontal line can show the maximum reaction that a typical firefighter can handle alone, 334 N [2], although it is unknown how this was determined. Equation (7) shows that a firefighter working alone on a backup line can only be expected to deliver the required flow rate when the jet diameter exceeds 24.4 mm.

In some cases the inputs to Eq. (7) are not known with sufficiency certainty, and an application of the Bernoulli equation becomes helpful. It is additionally assumed that (10) $A_2 < A_1$ and (11) the discharge coefficient [18,21] is unity. The Bernoulli equation yields

$$p_1 = \rho (v_2^2 - v_1^2) / 2. \quad (9)$$

Combining Eqs. (7) and (9) yields

$$R = \frac{2 A_2 p_1}{1 - (A_2 / A_1)^2}, \quad (10)$$

which is convenient when Q is unknown. Eqs. (7) and (9) can also be combined to obtain

$$R = (2 \rho Q^2 p_1 + \rho^2 Q^4 / A_1^2)^{0.5}, \quad (11)$$

which is convenient when A_2 is unknown. In Eqs. (9) – (11) the appropriate p_1 is the gage static pressure where the hose connects to the nozzle, assuming there is no partially closed valve or other pressure loss downstream of this.

Obtaining a low reaction with a high flow rate requires a large A_2 (Eq. 7) and a low p_1 (Eq. 10). This will result in a low throw distance and increased hose kinking. Although A_1 appears in Eqs. (10) and (11), its effect is small for typical firefighting hand lines such as those considered below.

Sub Topic: Fire

Equations (7), (10) and (11) apply best to smooth-bore nozzles. Reactions for fog and combination nozzles are approximated by Eq. (7) when jet divergence angle is small. Equations (10) and (11) do not apply to fog and combination nozzles with significant nozzle pressure losses. It has been suggested that fog and combination nozzles have the same reaction forces as solid streams [1-4], but Crapo [13] includes a correction for the jet divergence angle.

In the limit of $A_2 / A_1 \rightarrow 0$, Eqs. (10) and (11) reduce to these approximations:

$$R_{\text{approx}} = 2 p_1 A_2 \text{ and} \quad (12)$$

$$R_{\text{approx}} = Q (2 \rho p_1)^{0.5}. \quad (13)$$

Other than differences in constants, Eqs. (12) and (13) match the widely used NFPA predictions of reaction forces [1-4,12,13], for which the metric versions are

$$R_{\text{NFPA}} = 0.0015 p_1 d_2^2 \text{ and} \quad (14)$$

$$R_{\text{NFPA}} = 0.0226 Q p_1^{0.5}, \quad (15)$$

where d_2 is in mm, Q is in lpm, R_{NFPA} is in N, and p_1 is in kPag.

It is informative to compare R_{NFPA} from Eq. (14) with R from Eq. (10). The ratio R_{NFPA} / R depends only on the jet/hose diameter ratio, d_2 / d_1 . For $d_2 / d_1 \rightarrow 0$, $R_{\text{NFPA}} / R \rightarrow 0.95$. Typical firefighting hand lines involve d_2 / d_1 ratios of 0.5 – 0.8 [1-4,12,13], for which R_{NFPA} / R is 0.56 – 0.90. This could explain recommendations to augment the R_{NFPA} predictions by a safety factor of 2 – 3 [28].

Reactions encountered in practice may be lower than those predicted by Eqs. (7), (10), and (11). This is principally because a stiff hose combined with ground friction can support part of the reaction.

Conclusions

1. The tension in a bent hose is the pressure force plus the hose momentum flow rate, as expressed by Eq. (5). The hose tension is independent of the hose bend angle. If this tension is exceeded owing to anchor forces, the hose becomes straight.
2. The nozzle reaction equals the jet momentum flow rate. It must be overcome with a force applied by a firefighter or other anchor in the direction of the jet. Nozzle reaction can be predicted from Eq. (7), (10), or (11) depending on which geometric and flow quantities are known.
